

Pokémon TCG Schema

Table 1 - Player

The central actor in the system. Every action in the game, building decks, playing matches, purchasing items, is anchored to a player account. Storing currency (crystals, tickets) directly on the player row allows fast reads during shop interactions.

Table 2 – Card

Represents a unique card definition from the Pokémon TCG. Separating the definition from ownership avoids redundancy and lets card metadata be updated in one place.

Table 3 – Player Collection

The junction table linking players to cards they own. Because a player can hold multiple copies of the same card, a quantity column is included.

Table 4 – Deck

A saved deck configuration belonging to a player. TCG Live allows players to own multiple decks simultaneously. The `is_valid` flag is computed by the application layer to indicate whether the deck meets format rules (60-card limit, 4-copy maximum per card, at least one Basic Pokemon).

Table 5 – Deck Card

The composition of a deck which cards it contains and in what quantity. Acts as a many-to-many bridge between DECK and CARD. The unique constraint on (`deck_id`, `card_id`) ensures a card appears only once per deck row, with copies tracked via quantity.

Table 6 – Match

Records a completed game session between two players. Two foreign keys reference PLAYER, one for each player. `winner_id` is nullable to accommodate draws or disconnection outcomes.

Table 7 – Shop Item

Catalogue of purchasable items in the in-game shop: booster packs, avatar items, coins, sleeves, deck boxes, and battle passes.

Table 8 – Transaction

These store all the player transactions with the shop. These are essential to keep a track of player activity, and show the transactions to the player.
